January 19, 2021

- WordNet is a large lexical database of English (semantically-oriented)
- Nouns, verbs, adjectives and adverbs are grouped into sets of synonyms (synsets)
- Basis for grouping the words is their meanings.

Semantic Relations

- Hypernym, Supertype Color is a hypernym of Red.
- Hyponym, Subtype Purple is a hyponym of Color.
- Meronym, Part Finger is a meronym of Hand.
- Holonym, Whole Face is a holonym of Nose.
- Antonym, Opposites Long is a antonym of Short.
- Co-Hyponym Red an Blue are Co-Hyponym (they are both hyponyms of Color).
- Synonym Motorcar and automobile are synonyms

English WordNet online: http://wordnet.princeton.edu

noun

- S; (noun) wordnet (any of the machine-readable lexical databases modeled after the Princeton WordNet)
- S; (noun) WordNet, Princeton WordNet (a machine-readable lexical database organized by meanings; developed at Princeton University)

Consider the sentence in (1). If we replace the word motorcar in (1) with automobile, to get (2), the meaning of the sentence stays pretty much the same:

- 1. Benz is credited with the invention of the motorcar.
- 2. Benz is credited with the invention of the automobile.
 - ⇒ Motorcar and automobile are synonyms.

Let's explore these words with the help of WordNet

```
1 >>> from nltk.corpus import wordnet as wn
2 >>> wn.synsets("motorcar")
3  [Synset("car.n.01")]
```

- Motorcar has one meaning car.n.01 (=the first noun sense of car).
- The entity car.n.01 is called a synset, or "synonym set", a collection of synonymous words (or "lemmas"):

Synsets are described with a **gloss** (= definition) and some example sentences

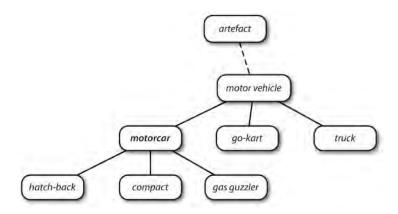

Unlike the words automobile and motorcar, which are unambiguous and have one synset, the word car is ambiguous, having five synsets:

```
>>> wn.synsets("car")
  [Synset("car.n.01"), Synset("car.n.02"), Synset("car.
      n.03"), Synset("car.n.04"), Synset("cable_car.n.
      01")1
  >>> for synset in wn.synsets("car"):
   ... print synset.lemma names()
   ["car", "auto", "automobile", "machine", "motorcar"]
  ["car", "railcar", "railway car", "railroad car"]
8 ["car", "gondola"]
9 ["car", "elevator car"]
10 ["cable car", "car"]
```

The WordNet Hierarchy

Hypernyms and hyponyms ("is-a relation")

- motor vehicle is a hypernym of motorcar
- ambulance is a hyponym of motorcar

The WordNet Hierarchy

```
>>> motorcar = wn.synset("car.n.01")
>>> types of motorcar = motorcar.hyponyms()
>>> types_of_motorcar[26]
Synset ("ambulance.n.01")
>>> sorted ([lemma.name() for synset in types of motorcar
    for lemma in synset.lemmas()])
["Model T", "S.U.V.", "SUV", "Stanley Steamer", "ambulance"
    . "beach waggon", "beach wagon", "bus", "cab", "
    compact", "compact car", "convertible", "coupe", "
    cruiser", "electric", "electric automobile", "
    electric_car", "estate_car", "gas_guzzler", "hack", "
    hardtop", "hatchback", "heap", "horseless_carriage", "
    hot-rod", "hot rod", "jalopy", "jeep", "landrover", "
    limo", "limousine", "loaner", "minicar", "minivan", "
    pace car", "patrol car", "phaeton", "police car", '
    police_cruiser", "prowl_car", "race_car", "racer", "
    racing car" ... 1
```

The WordNet Hierarchy

```
>>> motorcar.hypernyms()
[Synset("motor vehicle.n.01")]
>>> paths = motorcar.hypernym paths()
>>> len(paths)
2
>>> [synset.name() for synset in paths[0]]
["entity.n.01", "physical entity.n.01", "object.n.01"
    , "whole.n.02", "artifact.n.01", "instrumentality
    .n.03", "container.n.01", "wheeled vehicle.n.01",
     "self-propelled vehicle.n.01", "motor vehicle.n.
    01", "car.n.01"]
>>> [synset.name() for synset in paths[1]]
["entity.n.01", "physical entity.n.01", "object.n.01"
    , "whole.n.02", "artifact.n.01", "instrumentality
    .n.03", "conveyance.n.03", "vehicle.n.01", "
    wheeled vehicle.n.01", "self-propelled vehicle.n.
    01", "motor vehicle.n.01", "car.n.01"]
```

Meronyms and holonyms

- branch is a meronym (part meronym) of tree
- heartwood is a meronym (substance meronym) of tree
- forest is a holonym (member holonym) of tree

Relationships between verbs:

- the act of walking involves the act of stepping, so walking entails stepping
- some verbs have multiple entailments

```
1 >>> wn.synset("walk.v.01").entailments()
2 [Synset("step.v.01")]
3 >>> wn.synset("eat.v.01").entailments()
4 [Synset("swallow.v.01"), Synset("chew.v.01")]
5 >>> wn.synset("tease.v.03").entailments()
6 [Synset("arouse.v.07"), Synset("disappoint.v.01")]
```

Some lexical relationships can express antonymy:

You can see the lexical relations, and the other methods defined on a synset, using ${\tt dir}$ (). For example:

```
import nltk
from nltk.corpus import wordnet as wn

print(wn.synsets("motorcar"))

print(dir(wn.synsets("motorcar")[0]))
```

Two synsets linked to the same root may have several hypernyms in common. If two synsets share a very specific hypernym (low down in the hypernym hierarchy), they must be closely related.

```
>>> right = wn.synset("right whale.n.01")
2 >>> orca = wn.synset("orca.n.01")
3 >>> minke = wn.synset("minke whale.n.01")
  >>> tortoise = wn.synset("tortoise.n.01")
  >>> novel = wn.synset("novel.n.01")
  >>> right.lowest common hypernyms(minke)
  [Synset("baleen whale.n.01")]
  >>> right.lowest common hypernyms(orca)
  [Synset("whale.n.02")]
  >>> right.lowest common hypernyms(tortoise)
  [Synset("vertebrate.n.01")]
  >>> right.lowest common hypernyms(novel)
  [Synset("entity.n.01")]
```

We can quantify this concept of generality by looking up the depth of each synset:

```
1 >>> wn.synset("baleen_whale.n.01").min_depth()
2 14
3 >>> wn.synset("whale.n.02").min_depth()
4 13
5 >>> wn.synset("vertebrate.n.01").min_depth()
6 8
7 >>> wn.synset("entity.n.01").min_depth()
8 0
```

Similarity measures have been defined over the collection of WordNet synsets that incorporate this insight

- path_similarity() assigns a score in the range 0-1 based on the shortest path that connects the concepts in the hypernym hierarchy
- -1 is returned in those cases where a path cannot be found
- Comparing a synset with itself will return 1

```
1 >>> right.path_similarity(minke)
2 0.25
3 >>> right.path_similarity(orca)
4 0.166666666666666666
5 >>> right.path_similarity(tortoise)
6 0.076923076923076927
7 >>> right.path_similarity(novel)
8 0.043478260869565216
```

Similarity between nouns

- ("car", "automobile")
- synsets1("car") = [synset₁₁, synset₁₂, synset₁₃]
 nltk.corpus.wordnet.synsets("car")
- synsets2("automobile") = [synset₂₁, synset₂₂, synset₂₃]
 nltk.corpus.wordnet.synsets("automobile")
- consider all combinations of synsets formed by the synsets of the words in the word pair ("car", "automobile") [(synset₁₁, synset₂₁), (synset₁₁, synset₂₂), (synset₁₁, synset₂₃),...]
- determine score of each combination e.g.: synset₁₁.path_similarity(synset₂₁)
- ▶ determine the maximum score → indicator of similarity

???

Can you think of an NLP application for which semantic similarity will be helpful?

???

Can you think of an NLP application for which semantic similarity will be helpful?

Suggestion

Coreference Resolution:

I saw an orca. This whale was huge.

Polysemy

- The polysemy of a word is the number of senses it has.
- The noun dog has 7 senses in WordNet:

```
from nltk.corpus import wordnet as wn
num_senses=len(wn.synsets("dog","n"))

print(num_senses)
prints 7
```

We can also compute the average polysemy of nouns, verbs, adjectives and adverbs according to WordNet.

Polysemy of nouns

We can also compute the average polysemy of nouns.

► Fetch all lemmas in WordNet that have a given POS: nltk.corpus.wordnet.all_lemma_names (POS)

```
from nltk.corpus import wordnet as wn
all_lemmas=set(wn.all_lemma_names("n"))
print(len(all_lemmas))
prints 117798
```

▶ Determine meanings of each lemma: nltk.corpus.wordnet.synsets(lemma,pos) returns list of senses to a given lemma and POS, e.g. for "car"

```
1 from nltk.corpus import wordnet as wn
2 meanings=wn.synsets("car","n")
3 print(meanings)
```

Sum up the number of meanings of each lemma (restricted to nouns) and devide this by the total number of lemmas

Lesk Algorithm

- classical algorithm for Word Sense Disambiguation (WSD) introduced by Michael E. Lesk in 1986
- idea: word's dictionary definitions are likely to be good indicators for the senses they define

Lesk Algorithm: Example

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left

when combustible material is burned

Table: Two senses of ash

Lesk Algorithm: Example

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left

when combustible material is burned

Table: Two senses of ash

Score = number of (stemmed) words that are shared by sense definition and context

s1 s2 This cigar burns slowly and creates a stiff ash

Table: Disambiguation of ash with Lesk's algorithm

Interlude: Normalization

Once the text has been segmented into its tokens (paragraphs, sentences, words), most NLP pipelines do a number of other basic procedures for text normalization, e.g.:

- lowercasing
- stemming
- lemmatization
- stopword removal

Interlude: Lowercasing

Lowercasing:

```
import nltk

string = "The boy,s cars are different colors."

tokens = nltk.word_tokenize(string)

lower = [x.lower() for x in tokens]

print(" ".join(lower))

# prints

# prints

# the boy ,s cars are different colors .
```

- Often, however, instead of working with all word forms, we would like to extract and work with their base forms (e.g. lemmas or stems)
- Thus with stemming and lemmatization we aim to reduce inflectional (and sometimes derivational) forms to their base forms.

Interlude: Stemming

Stemming: removing morphological affixes from words, leaving only the word stem.

```
import nltk
string = "The boy, s cars are different colors."
tokens = nltk.word tokenize(string)
lower = [x.lower() for x in tokens]
stemmed = [stem(x) for x in lower]
print(" ".join(stemmed))
def stem(word):
    for suffix in ["ing", "ly", "ed", "ious", "ies", "ive", "es",
        "s" . "ment"]:
       if word.endswith(suffix):
           return word[:-len(suffix)]
  return word
# prints
# the boy .s car are different color .
```

Interlude: Stemming

Stemming:

```
import nltk
   import re
   string = "The boy, s cars are different colors."
   tokens = nltk.word_tokenize(string)
   lower = [x.lower() for x in tokens]
   stemmed = [stem(x) for x in lower]
   print(" ".join(stemmed))
   def stem(word):
        regexp = r " ^(.*?) (ing | ly | ed | ious | ies | ive | es | s | ment) ? 
        stem, suffix = re.findall(regexp, word)[0]
        return stem
14
15
   # prints
   # the boy ,s car are different color .
```

Interlude: Stemming

NLTK's stemmers:

Porter Stemmer is the oldest stemming algorithm supported in NLTK, originally published in 1979.

```
http:
```

```
//www.tartarus.org/~martin/PorterStemmer/
```

- ► Lancaster Stemmer is much newer, published in 1990, and is more aggressive than the Porter stemming algorithm.
- Snowball stemmer currently supports several languages: Danish, Dutch, English, Finnish, French, German, Hungarian, Italian, Norwegian, Porter, Portuguese, Romanian, Russian, Spanish, Swedish.
- Snowball stemmer: slightly faster computation time than porter.

Interlude: Stemming

NLTK's stemmers:

```
import nltk
   string = "The boy,s cars are different colors."
   tokens = nltk.word_tokenize(string)
   lower = [x.lower() for x in tokens]
   porter = nltk.PorterStemmer()
   stemmed = [porter.stem(t) for t in lower]
   print(" ".join(stemmed))
   # prints
   # the boy ,s car are differ color .
   lancaster = nltk.LancasterStemmer()
   stemmed = [lancaster.stem(t) for t in lower]
   print(" ".join(stemmed))
16
   # prints
   # the boy ,s car ar diff col .
```

Interlude: Stemming

NLTK's stemmers:

```
import nltk
   string = "The boy, s cars are different colors."
   tokens = nltk.word tokenize(string)
   lower = [x.lower() for x in tokens]
   snowball = nltk.SnowballStemmer("english")
   stemmed = [snowball.stem(t) for t in lower]
   print(" ".join(stemmed))
   # prints
10
   # the boy ,s car are differ color .
```

Interlude: Lemmatization

- stemming can often create non-existent words, whereas lemmas are actual words
- NLTK WordNet Lemmatizer uses the WordNet Database to lookup lemmas

```
import nltk
   string = "The boy, s cars are different colors."
   tokens = nltk.word tokenize(string)
   lower = [x.lower() for x in tokens]
   porter = nltk.PorterStemmer()
   stemmed = [porter.stem(t) for t in lower]
   print(" ".join(lemmatized))
   # prints the boy ,s car are differ color .
   wnl = nltk.WordNetLemmatizer()
   lemmatized = [wnl.lemmatize(t) for t in lower]
   print(" ".join(lemmatized))
12
   # prints the boy
   ,s car are different color .
```

Interlude: Stopword removal:

Stopword removal:

```
import nltk
   string = "The boy, s cars are different colors."
   tokens = nltk.word_tokenize(string)
   lower = [x.lower() for x in tokens]
   wnl = nltk.WordNetLemmatizer()
   lemmatized = [wnl.lemmatize(t) for t in lower]
   content = [x \text{ for } x \text{ in lemmatized if } x \text{ not in } n]tk.
       corpus.stopwords.words("english")]
   print(" ".join(content))
10
11
   # prints
   # boy ,s car different color .
```

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left
when combustible material is burned

Table: Two senses of ash

Score = number of (stemmed) words that are shared by sense definition and context

s1 s2 This cigar burns slowly and creates a stiff ash

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left
when combustible material is burned

Table: Two senses of ash

Score = number of (stemmed) words that are shared by sense definition and context

Scores	Context
s1 s2	This cigar burns slowly and
0 1	creates a stiff ash

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left
when combustible material is burned

when combustible material is burned

Table: Two senses of ash

Score = number of (stemmed) words that are shared by sense definition and context

Scores	Context
s1 s2	The ash is one of the last trees
???	to come into leaf

Sense Definition

s1: tree a tree of the olive family

s2: burned stuff the solid residue left when combustible material is burned

Table: Two senses of ash

Score = number of (stemmed) words that are shared by sense definition and context

Scores	Context
s1 s2	The ash is one of the last trees
1 0	to come into leaf

The definitions for "bank" are:

```
1 >>> from nltk.corpus import wsordnet as wn
2 >>> for ss in wn.synsets("bank"):
3 ... print(ss, ss.definition())
4 ...
5 Synset("bank.n.01") sloping land (especially the slope beside a body of water)
6 ...
```

Check implementation via

http://www.nltk.org/_modules/nltk/wsd.html

```
def lesk (context sentence, ambiguous word, pos=None,
    synsets=None):
    context = set(context_sentence)
    if synsets is None:
        synsets = wordnet.synsets(ambiguous_word)
    if pos:
        synsets = [ss for ss in synsets if str(ss.pos()) ==
             posl
    if not synsets:
        return None
    . sense = max(
        (len (context.intersection (ss.definition ().split ()))
            , ss) for ss in synsets
    return sense
```

- Information derived from a dictionary is insufficient for high quality Word Sense Disambiguation (WSD).
- Lesk reports accuracies between 50% and 70%.
- Optimizations: to expand each word in the context with a list of synonyms

Task

TASK TO SOLVE

In the Wikipedia article on Ada Lovelace,

- how many words refer to a relative? (excluding names)
- how many words refer to an illness?
- how many words refer to a science?

In each case: which words?

Task

TASK TO SOLVE

In the Wikipedia article on Ada Lovelace,

- how many words refer to a relative? (excluding names)
- how many words refer to an illness?
- how many words refer to a science?

In each case: which words?

Let's solve this using WordNet...

Step 1: Read in file

Read ada_lovelace.txt as one text string.

>>> print text
"Augusta Ada King, Countess of Lovelace (10 December 1815
27 November 1852), born Augusta Ada Byron and
now commonly known as Ada Lovelace, was an
English mathematician and writer chiefly known
for her work on Charles Babbages early mechanica
general—purpose computer, the Analytical Engine. ... "

Step 2: Sentence Splitting

Split the text into sentences:

```
1 >>> sentences = nltk.sent_tokenize(text)
2 ["Augusta Ada King, Countess of Lovelace ... "],
3 ["Her notes on the engine ... "],
4 ["Because of this , she is often ... "],
```

Step 3: Tokenize

Split the sentences in to tokens.

```
1 >>> print tokens
2 [["Augusta", "Ada", "King", ",", "Countess", ...],
3 ["Her", "notes", "on", "the", "engine", ...],
4 ["Because", "of", "this", ",", "she", "is", ...]
5 ...]
```

Step 4: Part-of-Speech tagging

Find the POS-tag of each token using NLTK's recommended POS tagger nltk.pos_tag.

```
1 >>> print tags
2 [[("Augusta", "NNP"), ("Ada", "NNP"), ...],
3 [("Her", "PRP$"), ("notes", "NNS"), ("on", "IN"), ...],
4 ...]
```

POS-tags

NLTK provides documentation for each tag, which can be queried using **nltk.help.upenn_tagset**.

- ► CC coordinating conjunction
- ► RB adverb
- IN preposition
- ► NN noun
- ▶ JJ adjective
- ► VB verb
- ▶ PRP pronoun

Step 5: Lemmatize

Put the lemma of each noun from the text into a list.

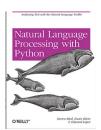

```
1 >>> from nltk.stem.wordnet import WordNetLemmatizer
2 >>> from nltk.corpus import wordnet
3 >>> lemmata = ...
4 >>> print lemmata
5 ["Augusta", "Ada", ..., "notes", ...]
```

Step 6: Find Hypernyms

These are the three hypernyms of interest (as there are multiple sysnsets for a lemma, we pick the first one in each list returned by nltk.wordnet):

```
1 >>> relative = wordnet.sysnsets("relative", pos="n")[0]
2 >>> relative = wordnet.sysnsets("scienece", pos="n")[0]
3 >>> relative = wordnet.sysnsets("illness", pos="n")[0]
```
